CAMARADES: Bringing evidence to translational medicine

Disclosures

- UK Commission for Human Medicines
- EMA Neurology SAG
- UK Animals in Science Committee
- Independent Statistical Standing Committee, CHDI Foundation
- Project co-ordinator, EQIPD IMI

This project has received funding from the Innovative Medicines Initiative 2 Joint Undertaking under grant agreement No 777364. This Joint Undertaking receives support from the European Union's Horizon 2020 research and innovation programme and EFPIA.

What is research?

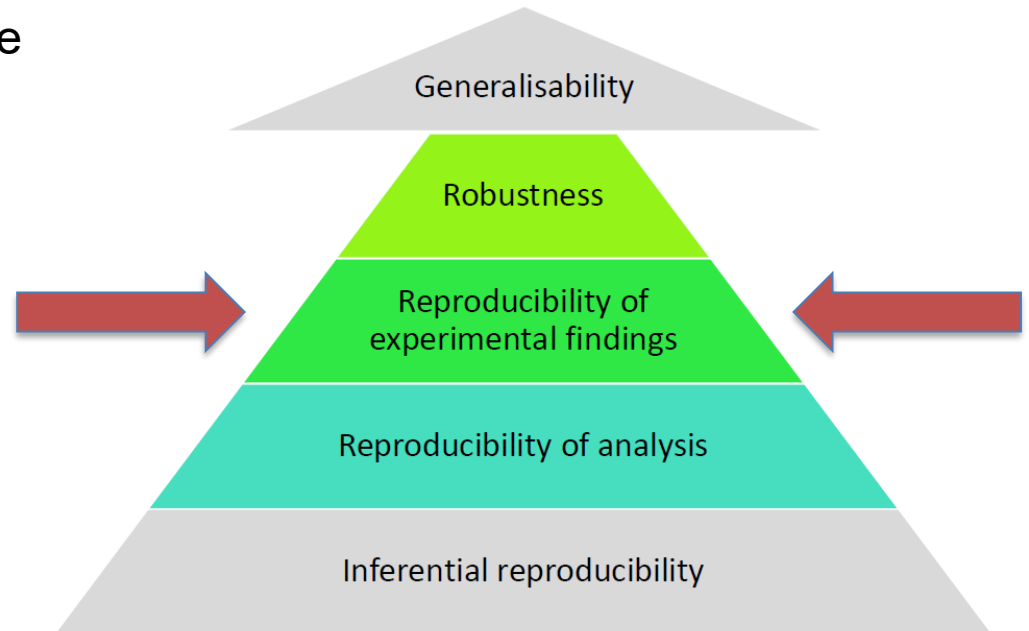

- Analysis and interpretation of observations
- Setting may be spontaneous or experimental
- Leads to a knowledge claim
- Usually involves a statistical analysis

Reproducibility and replication

“Reproducibility” related to the re-analysis of existing data following the same analytical procedures.

“Replication” was held to require the collection of new data, following the same methods.

Replication studies

1. **Retrospective** – Pharmaceutical companies sharing their historical experience when they have attempted replication

- | | |
|---------|-----------|
| – Bayer | 33% of 67 |
| – Amgen | 11% of 53 |

Selection bias (2 companies out of ?)

? Recall Bias

Replication studies

2. **Prospective** - Academic led, great attention given to faithfulness to original study design, adequate statistical power, preregistration

– Psychology	36% of 97	$ES_R=49\%$
– Cancer biology	40% of 10	
– Economics	61% of 18	$ES_R=66\%$
– Social sciences	62% of 21	$ES_R=54\%$

? Selection bias (how did they choose what to try to replicate?)

Claim

- Lack of reproducibility of experimental findings has been observed across such a wide variety of settings that it can be considered a general phenomenon
- Therefore, unless a field can demonstrate that it doesn't have a problem, it is reasonable to expect that it does

Neural Correlates of Interspecies Perspective Taking in the Post-Mortem Atlantic Salmon: An Argument For Proper Multiple Comparisons Correction

Craig M. Bennett^{1*}, Abigail A. Baird², Michael B. Miller¹ and George L. Wolford³

One mature Atlantic Salmon (*Salmo salar*) participated in the fMRI study. The salmon measured approximately 18 inches long, weighed 3.8 lbs, and was not alive at the time of scanning. It is not known if the salmon was male or female, but given the post-mortem state of the subject this was not thought to be a critical variable.

The task administered to the salmon involved completing an open-ended mentalizing task. The salmon was shown a series of photographs depicting human individuals in social situations with a specified emotional valence, either socially inclusive or socially exclusive. The salmon was asked to determine which emotion the individual in the photo must have been experiencing.

Several active voxels were observed in a cluster located within the salmon's brain cavity (see Fig. 1). The size of this cluster was 81 mm³ with a cluster-level significance of $p = 0.001$.

Either we have stumbled onto a rather amazing discovery in terms of post-mortem ichthyological cognition, or there is something a bit off with regard to our uncorrected statistical approach.

Winner of the 2012 Ignoble Prize for Neuroscience

Treatment of experimental stroke with low-dose glutamate and homeopathic *Arnica montana**

1026 interventions in experimental stroke

O' Collins et al, 2006

The originator study is incorrect

1. Most published research is false

Power = 20%

Alpha = 5%

Proportion of studies that are truly positive
("prior") = 10%

Chance that "significant" finding is true = 31%

Take 250 in vivo studies ...

STATUS QUO: Most studies have a statistical power of only 20% and a P value of 0.05, meaning many more false findings (PPV of 50%). This reflects a sample size of about 10 mice per study.

10 promising
molecules found

10 false
positives found

Psychology Replication Project (hat tip Anna Dreber)

For each study,

- p1 is the "prior" for the replication effort (derived from market)
- p0 is the **calculated** original "prior"
- p2 is the posterior

...

- $p_1 \propto$
 - strength of original evidence
 - expert critical appraisal
- For each study, also know power of replication study, so can predict probability of successful replication ($=p_1 \times \text{power}$)
- Averaging across 41 studies,
 $p(\text{rep}) = 0.53$, $p(\text{non-rep}) = 0.47$
 - \therefore expected non-replication = 19 studies
 - observed non-replication = 25 studies
 - attributable non-replication = 76%

The originator study is incorrect

1. Most published research is false
2. HARKing
3. Flexibility in data analysis (p-hacking)
4. Publication bias, selective outcome reporting bias

The originator study reports inflated effect size estimates

1. Designs which introduce risks of bias
2. Publication bias, selective outcome reporting bias

Risk of bias in animal studies

- Infarct Volume
 - 11 publications, 29 experiments, 408 animals
 - Improved outcome by 44% (35-53%)

Randomisation

Regulation of REM and Non-REM Sleep by Periaqueductal GABAergic Neurons

Franz Weber^{1,3}, Johnny Phong Hoang Do¹, Shinjae Chung^{1,3}, Kevin T. Beier², Mike Bikov¹,
Mohammad Saffari Doost¹ & Yang Dan ¹

Sample sizes. For optogenetic activation experiments, cell-type-specific ablation experiments, and in vivo recordings (optrode recordings and calcium imaging), we continuously increased the number of animals until statistical significance was reached to support our conclusions.

Trans-lational research

Cis-lational research

If $\Sigma(\text{knowledge}) < \text{threshold} \rightarrow \text{cis - lation}$

If $\Sigma(\text{knowledge}) > \text{threshold} \rightarrow \text{trans - lation}$

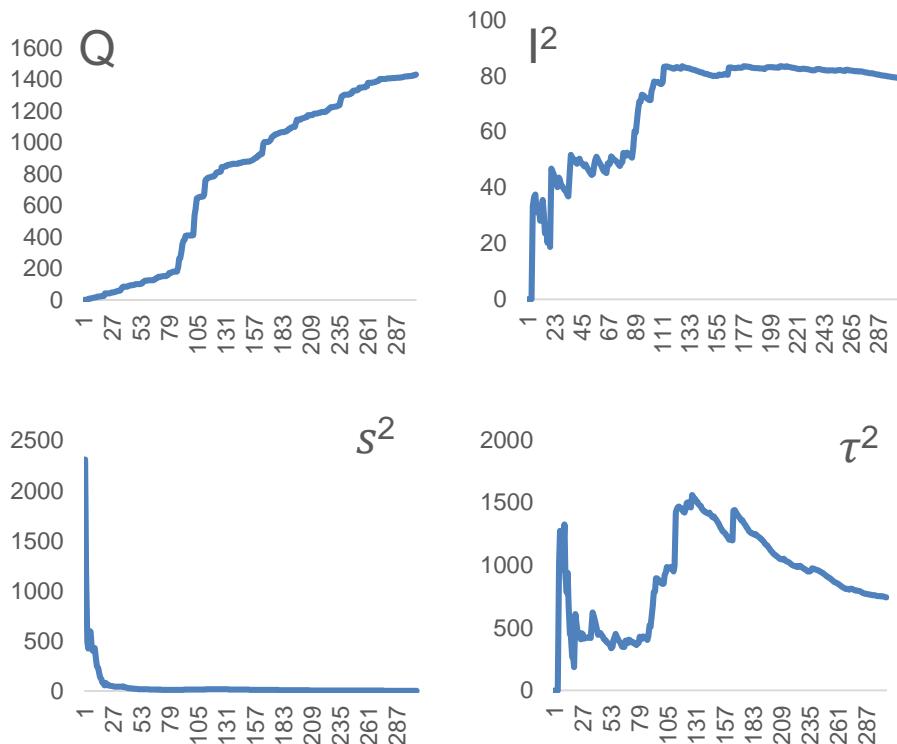

Cumulative random effects meta-analysis of tPA in stroke

Precision of estimation of effect of species, a known variable of interest

Cumulative random effects meta-analysis of tPA in stroke

Impact of known and latent variables:

As new studies are published (x-axis) then heterogeneity, estimated by Q or I^2 increases, and the variance of the overall effect s^2 falls. However, τ^2 (the “between study variance”) shows a different pattern, with an initial peak, then a second rise, then falling again. We see this also in the IL-1 RA dataset. It may be that the second fall in τ^2 corresponds to a dataset where possible heterogeneity has been adequately sampled.

Impossible replication – the Morris Water Maze

Both studies may be correct Reaction norms (Voelkl 2016)

Lifespan in worms

Source of variation	Developmental Rate	Fertility
Genetic	83.1%	63.3%
Between labs	8.3%	7.9%
Within labs	3.8%	5.6%
Individual	4.8%	23.3%

Figure 3: Variation in longevity within labs for each replicate plate for eight natural isolates of *C. briggsae*.

Lucanic et al Nature Comms 2017

What should we do?

1. increase the probability that published research is true
2. establish a framework to select efficiently which research findings we should attempt to replicate
3. develop strategies to evaluate the robustness of key research findings

...with $p < 0.01$, power @ 80%

PROPOSED STANDARDS: To achieve a PPV of 95%, study results would need a P value of 0.01 and a large enough sample size to reach 80% statistical power (typically >75 mice per study).

40 promising
molecules found

2 false
positives found

Researchers are different ...

Research Improvement Strategy

How might we do this?

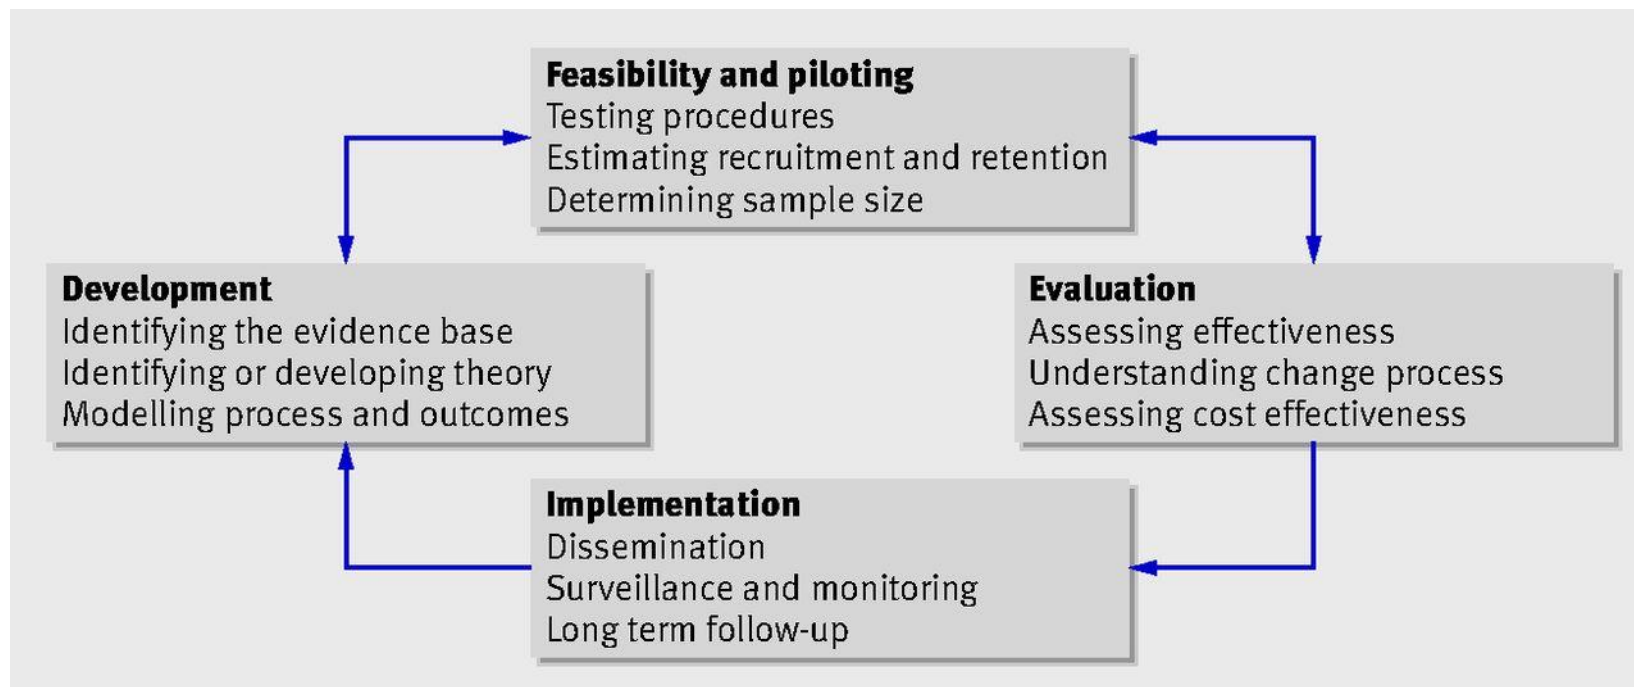

- There are many interacting components
- There are a number of novel behaviours required by those delivering or receiving the intervention, and some of these changes are challenging
- Many groups and organisational levels are targeted by the intervention
- There is a wide range of possible outcome measures
- Interventions will likely need tailoring to local environment

Complex Interventions

“Best practice is to develop interventions systematically, using the best available practice and appropriate theory, then to test them using a carefully phased approach, starting with a series of pilot studies targeted at each of the key uncertainties in the design, and then moving on to an exploratory and then a definitive evaluation. The results should be disseminated as widely and as persuasively as possible, with further research to assist and monitor the process of implementation”

Peter Craig et al. BMJ 2008;337:bmj.a1655

Peter Craig et al. BMJ 2008;337:bmj.a1655

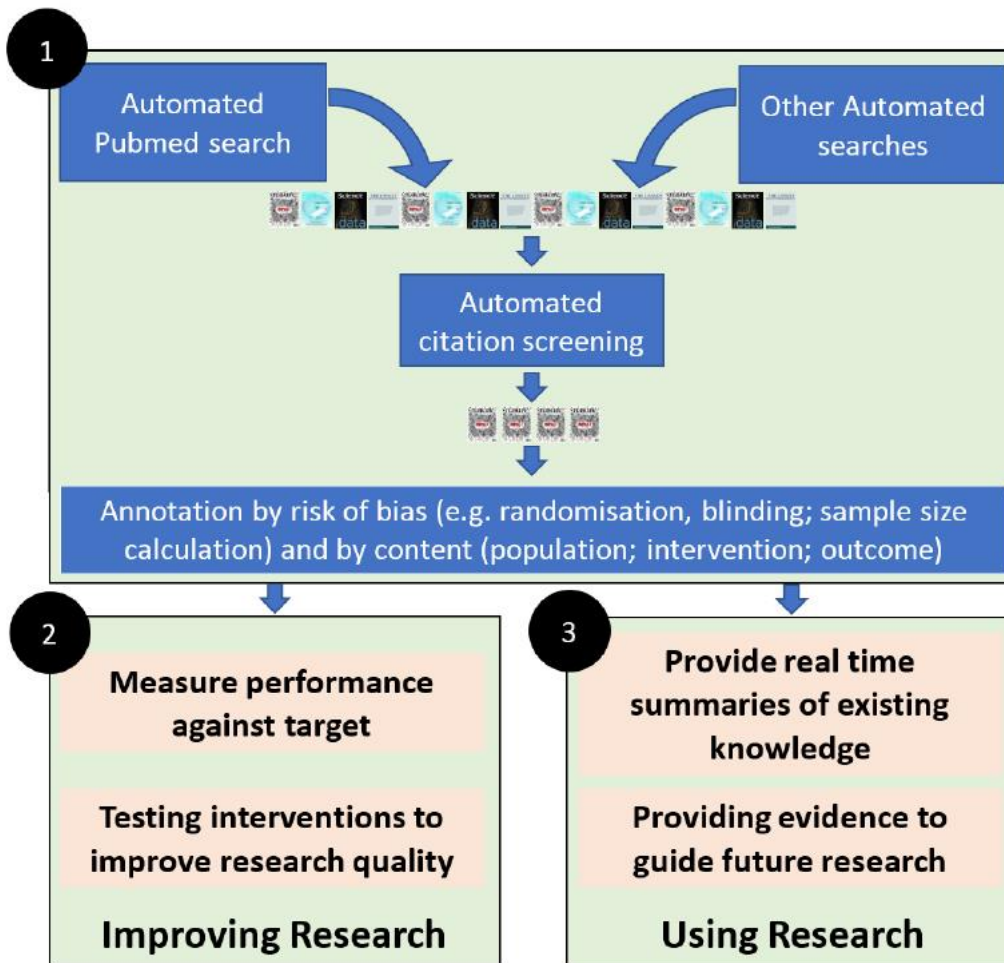

Possible approaches

Training	Undergraduate Post graduate Faculty	Mandatory or elective? As a requirement for conducting <i>in vivo</i> research?	Does certificated training to an enhanced level provide an advantage in grant application success rates?
Incentives	access to resources such as travel funds for junior staff, publication costs, near miss funding	<ul style="list-style-type: none">• to pre-register study protocols• for BioRxiv publication• for Open Access publication• for making data and code availabe	
Support	Methodological support for review of experimental design prior to grant submission Review of manuscripts prior to journal submission Review of proposed research methodology at stage of requesting to animal house that procedure be permitted		
Admin	Can internal processes be made less burdensome while still achieving their purpose Can changes to institutional policies for appointment and promotion be used to encourage research improvement?

Data Analysis Plan: Open Science Framework (September 2017)

Funding: MRC, NC3Rs, BBSRC & Wellcome Trust

Ethics: BMJ Ethics Committee

Recommendations

- Every institution which conducts research should have a formal Research Improvement Strategy
- Funders should consider the high returns on Replication studies (30-50% chance of revising existing knowledge)
- Pivotal research findings should be challenged in prospective multicenter replication studies prior to exploitation

Biomedical research investment

- \$300bn globally, €50bn in Europe
- Glasziou and Chalmers claim 85% wasted
- Even if waste is only 50%, improvements which reduced that by 1% would free \$3bn globally, €500m in Europe, every year.
- Investing ~1% of research expenditure in improvement activity would go a long way
